

Dietary Supplement Laboratory Quality Assurance Program
Exercise E
Final Data Report

October 13, 2010

Thank you for your participation in Exercise E of the Dietary Supplements Laboratory Quality Assurance Program. This exercise attracted a record signup of all exercises to date, and more importantly, had the highest percentage of data returned. The attached final report contains five sections: an overview of the data treatment and representation; graphs displaying the community performance; general recommendations from the exercise, your individual laboratory results, and certificates of participation.

Please check the data from your laboratory throughout both reports and make sure that it agrees with the data that you submitted. If you do not agree with the data in this report, please let us know so that we can correct it.

If you have any questions or suggestions, please let us know.

Best regards,

DSQAP Team

INTRODUCTION

This report consists of several parts:

[Overview](#) of Data Treatment and Representation: a general description of the statistical treatment of the data and how to read the plots.

Data: a section that includes tables and graphical representations of the data for the analytes tested in this exercise, points to consider when examining the data and recommendations from Exercise E when appropriate.

OVERVIEW OF DATA TREATMENT AND REPRESENTATION

STATISTICS

Your individual data table and graphs contain information about your performance relative to that of the other participants in this exercise and relative to a target around the expected result.

DATA TABLES

The raw data for each analyte in each sample are provided in tabular form within each section. Please check your data for transcription errors.

GRAPHS

Two graphs are provided for each analyte in each sample, one which plots the results for the sample only (View 1) and one which plots the lab results for the sample against the lab results for the control (View 2). Both views include the consensus values and the target values (where appropriate).

View 1

In this view, individual laboratory data are plotted with the individual laboratory standard deviation. The black solid line represents the consensus median and the black dotted lines represent the consensus variability calculated as $2 \times \text{MADe}$. The center of the region between the red lines represents the target zone (when available). The target value is the NIST certified value (or an approximation where appropriate) and is bounded by two times the pooled standard deviation ($2 \times s_{\text{total, pooled}}$) of the participants or the NIST uncertainty (U_{95}), whichever is larger, creating a target zone for “acceptable” performance. With this view, it is relatively easy to determine if a laboratory falls within the target zone and to compare where the target zone lies relative to the consensus zone. In most cases, the target zone falls within the consensus zone, which is the expected result. One program goal is to bring the consensus zone closer together and closer to the target value.

View 2

In this view, the results reported for the sample are plotted against the results for the control. The red box represents the target zone for the control (x-axis) and the sample (y-axis) and the blue dotted lines represent the analogous information for the consensus zone.

This view provides additional information to complement View 1. For example, if your values are low (or high) for both the control and sample, you may have calibration issues. If your laboratory falls into this category, you may want to investigate how your calibrants are prepared as well as the purity of your calibrant material.

[Return to Table of Contents](#)

INDIVIDUAL DATA TABLE

Section 1 of the data table contains your results, including your mean, standard deviation, and Z-score (when appropriate). Please check these and make sure that you agree with the mean and standard deviation reported in the table. Your individual lab code can be found in the upper left corner of each individual data table.

The significance of the Z-score is as follows:

- $|Z| < 2$ indicates that your result is considered to be within the community consensus value.
- $2 < |Z| < 3$ indicates that your result is considered to be marginally different from the community consensus value.
- $|Z| > 3$ indicates that your result is considered to be significantly different from the community consensus value.

A Z-score does not necessarily indicate whether or not your values are correct; instead, it is a reflection of how close your values are to the rest of the community.

Section 2 of the data table contains the community results, including the median value for each analyte, the MADe (a robust estimate of the standard deviation), and the minimum and maximum values reported for the analyte.

Section 3 of the data table contains the NIST results. In most cases, the assigned value and the U_{95} confidence interval have been determined with two independent analytical methods. At least six samples have been tested with each of the methods and duplicate sample preparations from the sample package have been included, allowing the U_{95} to encompass variability due to inhomogeneity within and between packages.

NUTRITIONAL ELEMENTS IN BREAKFAST CEREALS

This study was different than the other studies in this exercise; in addition to providing laboratory comparability and proficiency information, it was also designed to show the effect of sample type and sample preparation on both within- and between-laboratory comparability of results. The results from the complete study will take longer to analyze, therefore only the comparability data are presented in this report. Participants will be notified of the extended results as soon as they are available.

Six cereal samples were sent with this study:

- Cereal A is SRM 3233 Fortified Breakfast Cereal, a ground, sieved wheat-based cereal.
- Cereal B is a ground wheat-based cereal.
- Cereal C is Cereal B, prior to grinding.
- Cereal D is a ground rice-based cereal.
- Cereal E is Cereal D prior to grinding.
- Cereal F is a hand crushed 1:1 mixture (by mass) of Cereals C and E.

Assuming that all of the samples are homogeneous, the results for the pairs of samples (B/C and D/E) should be identical and sample F is expected to be an approximate average of the two. The differences in variability between the ground and flake cereals will be examined to evaluate the sampling effects, and will be reported at a later date.

- Twenty-three laboratories enrolled in this exercise and received samples; 19 laboratories reported results (83 %).
- Since homogeneity was established only for sample A in this study, it is the only sample with target values. NIST is a blinded participant for the remaining samples in this study.
- Overall, the majority of laboratories are achieving relatively precise ($< 3\%$) measurements that fall within the consensus range. The precision was better for Fe than for Ca and Zn.

NUTRITIONAL ELEMENTS IN BREAKFAST CEREALS

[Return to Table of Contents](#)

NIACINAMIDE IN FORTIFIED BREAKFAST CEREAL

Exercise E is the third exercise in which participants have measured niacinamide. The focus on niacinamide arose because all previous DSQAP water-soluble vitamin studies demonstrated surprisingly scattered results. Relative to the other water-soluble vitamins, niacinamide is relatively stable and in relatively high abundance, thus it is a good candidate for methodological problem solving. In Exercise C, for the measurement of niacinamide in infant formula (SRM 1849) with Ephedra-Containing Protein Powder (SRM 3244) as a control, laboratory performance was poor, with fewer than half of the laboratories reporting results within the a relatively wide target area. A study in Exercise D paired an infant formula with SRM 1849 Infant/Adult Nutritional Formula as a control. Participants in Exercise D were also provided with a vial containing 500 mg of USP Niacinamide for use as a calibrant. The results in Exercise D demonstrated significant improvement, highlighting the importance of the selection of control and calibration materials.

As a final arm of the study, a very different sample matrix was sent for the measurement of niacinamide. In Exercise E, a ground breakfast cereal was sent with candidate SRM 3233 Fortified Breakfast Cereal as a control material.

- Seventeen laboratories enrolled in this exercise and received samples; 14 laboratories reported results (82 %).
- The consensus value was tighter for the unknown cereal than the control and there were more outliers for the measurement of the control than for the unknown.
- Examination of the two dimensional data plot shows that (with the exception of the significant outliers) results are on a diagonal line indicating that there may be a significant amount of variation in the calibrant materials used by different laboratories for the measurement of niacinamide.

Recommendations:

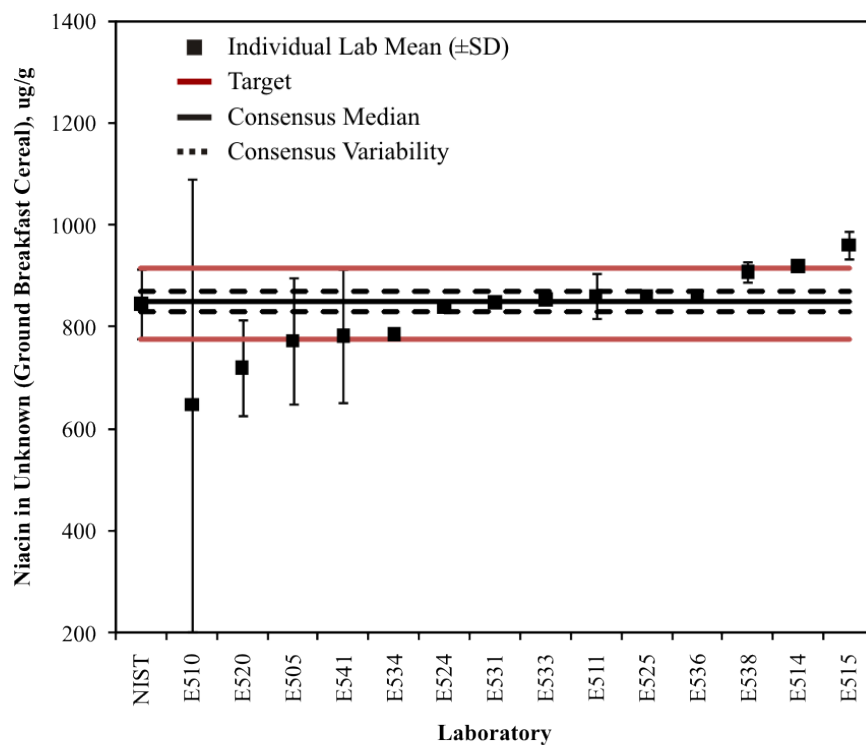

- Always be sure to characterize/qualify calibration materials and look for impurities in the materials.
- The use of well-paired control/sample materials is important.

CATECHINS IN GREEN TEA

SRM 3256 Green Tea-Containing Tablets was used as the sample with SRM 3255 *Camellia sinensis* Extract as a control material. The reporting spreadsheet specifically asked for epicatechin, epicatechin gallate (ECG), epigallocatechin (EGC), epigallocatechin gallate (EGCG), gallocatechin (GC), and gallocatechin gallate (GCG), however, it was understood that not all methods separate all of the compounds that calibration standards are not necessarily available for each of the analytes.

The data for the green tea study were more scattered than the other studies in this exercise. In order to effectively determine the source of this scatter, it is necessary to investigate chromatograms (are analytes completely resolved from each other?) and to further investigate calibration and extraction schemes. The control values are in much better agreement than the sample values; as the control does not require extraction, this points to possible extraction biases for the study overall.

- Eighteen laboratories signed up for this exercise and received samples; 14 laboratories reported data (78 %).
- Laboratories varied greatly on performance from analyte to analyte. For example, the reported results for one analyte might be right on target but the results for another analyte might be very high.
- Is it possible that extraction methods are causing epimerization? Several labs were low on epicatechin and high on catechin.
- Does epimerization matter for your purposes, or is the measurement of total catechins sufficient?
- Almost all laboratories reported high values for EGCG, and the consensus zone was entirely above the target zone. Is another compound coeluting with EGCG and causing a bias to higher values?
- A total catechin estimation was made as the sum of the reported values for all the catechins for each laboratory. Overall the results were more reassuring, with the consensus range falling in the center of the target zone for the sample. The two-dimensional data plot indicates a strong possibility of a calibration issue.

β -CAROTENE IN MULTIVITAMIN TABLETS

Exercise D included a study of β -carotene in botanical oils. Unfortunately, during the course of the study it was discovered that the β -carotene in the carrot extract in oil was degrading rapidly, making the interpretation of the results close to impossible. In Exercise E, SRM 3280 Multivitamin/Multielement Tablets were sent to participants as the sample and SRM 3251 *Serenoa repens* Extract was sent as a control. The amount of total β -carotene in the multivitamin tablet is approximately 10 times the amount in the control material and the extraction of the β -carotene from the multivitamin tablet is significantly more challenging than SRM 3251.

- Twenty laboratories enrolled in this exercise and received samples; 14 laboratories reported results (70 %).
- Due to the extraction methods required for the multivitamin tablet, the total β -carotene is the best measure for laboratory comparability.
- Most laboratories that were not in the target range reported total β -carotene values that were high for the control and low for the sample.
- 53 % of the laboratories that reported data were within the target range for the measurement of β -carotene in the sample.

Recommendations:

- The low values reported for the sample are likely due to extraction problems, either an incomplete extraction or the β -carotene isomerized or degraded, leading to a lower value.
- Check molar absorptivity used for the determination of calibrant concentration. If different laboratories are using different values, there is the potential for wide variation in the results.

AFLATOXINS IN PEANUT PRODUCTS

The Good Manufacturing Processes (GMPs), established by the US Food and Drug Administration (FDA), now apply to all dietary supplement manufacturers and specify the necessity of testing for contaminants and toxins as well as active/marker compounds. For this reason, the DSQAP will be including more toxins and contaminant studies in future exercises.

Ground whole peanuts were sent as a sample with SRM 2387 Peanut Butter as a control. The samples were purchased from The Food and Environment Research Agency's Food Analysis Performance Assessment Scheme (FAPAS) in the UK. They were analyzed by 65 laboratories between March 2009 and April 2009. The levels of aflatoxins B₁ and B₂ in SRM 2387 were measured as part of an interlaboratory intercomparison exercise. Aflatoxins G₁ and G₂ were not measured in the SRM.

- Seven laboratories enrolled in this exercise and received samples; 5 laboratories reported results (71 %).
- All five laboratories that provided data for aflatoxin B₁ performed well.
- All four laboratories that provided data for aflatoxin B₂ performed well.
- The three laboratories that provided data for aflatoxins G₁ and G₂ performed well.
- The total aflatoxins were reported by the five laboratories and all performed well.

Considerations:

- This study did not receive the number of participants we anticipated. What toxins and contaminants are most important for your laboratories?

RECOMMENDATIONS

There were several global issues that we noticed while reviewing the data; please consider these recommendations as they may help improve measurement accuracy and precision.

When a target range is provided for a control, the information should be used as a quality self check. The target value should NOT be used to determine a scaling factor. The matrices are often significantly different between the sample and control. Analytes may be extracted differently from the two materials, thus the adjustment factor for recovery in the control would not be valid for the sample.

Sample cleanup with solid-phase extraction or filters may be useful prior to analysis. However, the cleanup method should always be tested with a calibrant during method development to ensure that the analytes of interest are not binding to the cleanup substrate. Organic analytes are especially likely to bind to nylon or other polymer-based filters.

Evaluation of the purity and stability of calibration materials is very important; this point is highlighted by the measurement of niacinamide in Exercises C, D, and E. There are several factors to consider when evaluating calibration materials:

- Does the labeled purity make sense or are there a number of “extra” peaks in the chromatogram that are unaccounted for?
- Are you storing crystalline materials properly? (are light-sensitive compounds stored away from light? Do you store materials cold or under inert gases? Do you bring them to room temperature in desiccators?)
- How long does your laboratory store calibration materials? Have you evaluated the stability under your storage conditions?

QUESTION

Related to catechins in green tea and also β -carotene, do epimers and isomers matter to your laboratory or is it more important for you to measure the total analyte accurately and precisely?
