Ethylene Purification

An Ideal Molecular Sieve for Acetylene Removal from Ethylene with Record Selectivity and Productivity

Bin Li, Xili Cui, Daniel O'Nolan, Hui-Min Wen, Mengdie Jiang, Rajamani Krishna, Hui Wu, Rui-Biao Lin, Yu-Sheng Chen, Daqiang Yuan, Huabin Xing,* Wei Zhou,* Qilong Ren, Guodong Qian, Michael J. Zaworotko,* and Banglin Chen*

Realization of ideal molecular sieves, in which the larger gas molecules are completely blocked without sacrificing high adsorption capacities of the preferred smaller gas molecules, can significantly reduce energy costs for gas separation and purification and thus facilitate a possible technological transformation from the traditional energy-intensive cryogenic distillation to the energy-efficient, adsorbent-based separation and purification in the future. Although extensive research endeavors are pursued to target ideal molecular sieves among diverse porous materials, over the past several decades, ideal molecular sieves for the separation and purification of light hydrocarbons are rarely realized. Herein, an ideal porous material, SIFSIX-14-Cu-i (also termed as UTSA-200), is reported with ultrafine tuning of pore size (3.4 Å) to effectively block ethylene (C_2H_4) molecules but to take up a record-high amount of acetylene (C₂H₂, 58 cm³ cm⁻³ under 0.01 bar and 298 K). The material therefore sets up new benchmarks for both the adsorption capacity and selectivity, and thus provides a record purification capacity for the removal of trace C_2H_2 from C_2H_4 with 1.18 mmol g⁻¹ C_2H_2 uptake capacity from a 1/99 C_2H_2/C_2H_4 mixture to produce 99.9999% pure C_2H_4 (much higher than the acceptable purity of 99.996% for polymer-grade C₂H₄), as demonstrated by experimental breakthrough curves.

Porous materials offer promise for the separation and purification of industrial commodity chemicals through adsorbent- and/or membrane-based separation technologies and thus might enable a transition from established separation technologies such as cryogenic distillation, which currently accounts for 10-15% of the world's energy consumption.^[1-4] Although such promise has not been fully fulfilled, extensive research efforts have indeed led to progress over the past several decades. For example, the discovery of the molecular gate adsorbent ETS-4 has initiated the industrial scale nature gas separation.[5,6]

Pore tuning and pore functionalization are two powerful approaches to introduce molecular sieving and preferential binding effects and thus are very important to target porous materials for the efficient gas separation and purification, as clearly demonstrated in ETS-4 series and zeolite LiX materials for CH_4/N_2 and $N_2/$ O_2 separations, respectively.^[5,7] Whereas

traditional zeolite-type materials are quite limited in terms of tuning pore size and functionalization, basically through control of the thermal activation and substitutions of metal cations, microporous metal-organic frameworks, and related classes of materials have provided us the rich chemistry to realize fine pore tuning and functionalization, and thus target materials for gas separation and purification through the judicial choices of metal clusters and organic linkers, framework topology design, framework interpenetration control, and immobilization of specific functional sites.^[8-16] Indeed, a number of microporous metal-organic frameworks (MOFs) have been realized to address a diverse range of gas separations over the past decades through a synergistic approach to pore tuning and functionalization.^[17-27] Recent progress on this topic for the separation of C_2H_2/C_2H_4 and C_3H_6/C_3H_8 is of particularly interest.^[28,29] In the former case of SIFSIX-2-Cu-i, the trade-off between adsorption capacity and selectivity for separating the challenging gas mixtures of C_2H_2/C_2H_4 has been significantly minimized; in the latter case, NbOFFIVE-1-Ni exhibits a molecular sieving effect for C₃H₆/C₃H₈ separation. Although these two porous materials exhibit benchmark performance for the above-mentioned gas separations, they still suffer from certain degree of the trade-off effects: the C_2H_2/C_2H_4 selectivity (S_{ac}) of SIFSIX-2-Cu-i does not preclude coadsorption of the larger molecule, C_2H_4 , when C_2H_2 is a minor impurity; NbOFFIVE-1-Ni can adsorb small amounts of the smaller molecule of C3H6, particularly under low pressure of 0.1 bar (\approx 5.3 cm³ g⁻¹), deviating from the ideal molecular sieves (ideal molecular sieves are defined as those which can completely block the larger gas

molecules and take up large amount of the smaller gas molecules from gas mixtures). Realization of ideal molecular sieves can certainly enable ultrahigh selectivity and working capacity for diverse gas separations and thus improve the product purity and adsorbent productivity in the adsorption-based separation process that is driven by pressure swing adsorption, thermal swing adsorption, or membrane-based operations, to result in the significant energy savings.^[30–35] To the best of our knowledge, there are only a few reported molecular sieves for carbon capture and separation of olefin/paraffin.^[29,36–41] We target this matter herein through the study of SIFSIX-14-Cu-i (UTSA-200), a new variant of SIFSIX-2-Cu-i, to realize the ideal molecular sieve for separation and purification of C_2H_2/C_2H_4 mixtures with the record selectivity and C_2H_4 productivity ever reported.

Structural and modeling studies have indicated that the pores of about 4.4 Å in SIFSIX-2-Cu-i remain slightly larger than the size of C_2H_4 (kinetic dimensions 4.2 Å)^[42] and thus cannot exhibit a sieving effect for C_2H_4 (Figure S3, Supporting Information). We speculated that if a shorter organic linker of 4,4'-azopyridine (azpy, 9.0 Å) instead of 4,4'-dipyridylacetylene (dpa, 9.6 Å) is used to construct the isoreticular SIFSIX-14-Cu-i /UTSA-200 (Figure 1), the resulting microporous material was expected to exhibit a smaller pore size of \approx 3.3–4.0 Å that might completely block C_2H_4 molecules while enhance the affinity of the functional SiF₆^{2–} sites toward C_2H_2 , thus targeting an ideal molecular sieve for the extremely highly efficient removal of C_2H_2 from a 1/99 C_2H_2/C_2H_4 mixture to produce high purity of C_2H_4 in a much higher production scale than SIFSIX-2-Cu-i. Our experimental and simulation studies verify this hypothesis,

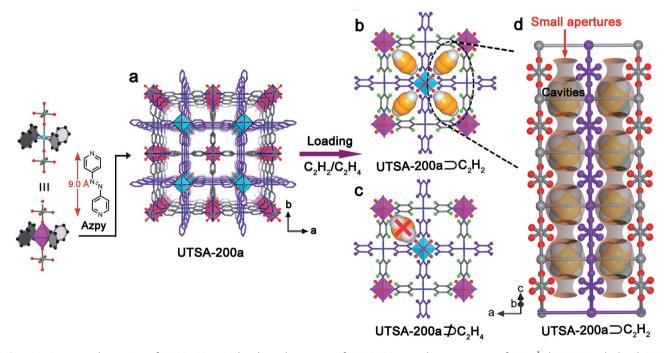

Figure 1. Structure description of UTSA-200a. a) The channel structure of UTSA-200a reveals a pores size of \approx 3.4 Å. b) DFT-D-calculated C₂H₂ adsorption models in UTSA-200a, revealing that this pore size enables the passage of C₂H₂ molecules. c) Simulated C₂H₄ adsorption in UTSA-200a indicating that the C₂H₄ molecule are too large to pass through the pores. d) Schematic illustration of ideal molecular sieves based on the structure of UTSA-200a \Box_2 H₂, in which larger cavities suitable for strongly binding C₂H₂ molecules are interconnected by narrow apertures that serve as sieves for C₂H₄ but not for C₂H₂. ADVANCED MATERIALS www.advmat.de

and we report herein the structure, adsorption isotherms, simulated and experimental breakthrough curves of SIFSIX-14-Cu-i (UTSA-200). These data reveal that SIFSIX-14-Cu-i (UTSA-200) is the new benchmark porous material for the removal of C_2H_2 from C_2H_4 in a 1/99 mixture that mimics that present in large-scale industrial ethylene production processes.

Reaction of azpy with CuSiF₆ afforded saffron prism-shaped crystals of $[Cu(azpy)_2(SiF_6)]_n$ (see the Supporting Information for synthetic and crystallographic details). The single-crystal X-ray diffraction analysis revealed that UTSA-200 has doubly interpenetrated nets that are isostructural to the nets in SIFSIX-2-Cu-i.^[18] After removing guest molecules, we further collected the desolvated structure, that is, UTSA-200a, by using neutron powder diffraction experiments at 200 K. As revealed by Figure 1a, the use of the shorter azpy instead of dpa as a linker offers: (i) a commensurate reduction on the pore size; and (ii) a certain degree of tilting of the pyridine moieties, which are rotated by around 28 degrees with respect to the crystal axis (Figure S4, Supporting Information). The SiF₆²⁻ pillars and pyridine rings are interconnected through a strong hydrogen bonding of C-H...F (2.326 Å) to restrict the rotation of pyridine rings. This tilt of pyridine rings thereby results in the pore size of UTSA-200a being notably reduced to 3.4 Å. In addition, the channels of UTSA-200a exhibit the features of ideal molecular sieves, in which larger cavities functionalized with the SiF₆²⁻ binding sites are interconnected by narrow apertures of 3.4 Å (molecular sieving dimension, Figure 1d; Figure S5, Supporting Information). This narrow aperture size was further confirmed by the calculated pore size distributions, where the pore sizes of UTSA-200a are less than 3.6 Å (Figure S6, Supporting Information), in good agreement with the results of structural analysis. We note that the aperture size of 3.4 Å is much smaller than the kinetic diameter of C2H4 molecule (4.2 Å) but slightly larger than that of C_2H_2 (3.3 Å), consistent with the potential for selective molecular sieving in C_2H_2/C_2H_4 separations.

We first performed detailed modeling studies using firstprinciples dispersion-corrected density functional theory (DFT-D) method on UTSA-200a and compared the results with SIFSIX-2-Cu-i to evaluate the possible sieving effect on C₂H₂/C₂H₄ molecules. In the 2-fold interpenetrated structure of SIFSIX-2-Cu-i, the window size of 4.4 Å is larger than both C₂H₂ and C₂H₄, thereby allowing both C₂H₂ and C₂H₄ molecules to enter the cavities (Figure S3, Supporting Information). Each adsorbed C₂H₂ or C₂H₄ molecule is simultaneously bound by two SiF₆²⁻ sites from different nets through cooperative C-H-F H-bonding (2.015 Å for C2H2 and 2.186 Å for C_2H_4).^[28] When the aperture size was reduced to 3.4 Å in UTSA-200a, our computational results indicated that the contracted aperture size still allows C2H2 molecules to enter the pore cavities and bind in the same fashion upon adsorption (Figure 1b). The calculated distance of C-H…F H-bonding in UTSA-200a is shorter (1.900 Å) than that in SIFSIX-2-Cu-i (Figure S7, Supporting Information). In contrast, when loading a C_2H_4 molecule into the pores, we found that the C_2H_4 molecule would have inevitable space overlapping with the pore walls of UTSA-200a (Figure 1c), suggesting that the size of C2H4 may mismatch with the host framework and thereby to be size excluded. These calculated studies support that the

contracted pore size of UTSA-200a (vs SIFSIX-2-Cu-i) might enable sieving of C_2H_2 from $C_2H_4.$

The performance of UTSA-200a was determined by examining its gas sorption and separation properties. As illustrated in **Figure 2a**, UTSA-200a exhibits almost no N₂ uptake at 77 K, indicating that even N₂ (3.64 Å) is blocked at this low cryogenic temperature because of the small aperture size. On the other hand, for CO₂ (kinetic diameter 3.3 Å), a high amount of CO₂ is absorbed (153 cm³ g⁻¹) at 196 K and 1 bar with type I sorption behavior characteristic of microporous materials. The Brunauer–Emmett–Teller (BET) surface area and pore volume were calculated to be 612 m² g⁻¹ and 0.27 cm³ g⁻¹, respectively, slightly lower than SIFSIX-2-Cu-i (735 m² g⁻¹ and 0.31 cm³ g⁻¹).

Pure component equilibrium adsorption isotherms for C₂H₂ and C₂H₄ were measured at 298 K up to 1 bar, as presented in Figure 2b. Detailed analysis revealed that UTSA-200a exhibits a steep and high C_2H_2 uptake of 116 cm³ cm⁻³ at 298 K and 1 bar. This value is comparable to the uptake of SIFSIX-2-Cu-i and is expected thanks to their similar pore chemistry. However, contraction of pore size in UTSA-200a was found to enable higher uptake than SIFSIX-2-Cu-i within the low pressure of 0.025 bar (Figure 2c). At 0.01 bar, which is an indicator of the C_2H_2 capture ability of adsorbents from a C_2H_2/C_2H_4 mixture (1/99, v/v), UTSA-200a exhibits notably enhanced C₂H₂ uptake (58 cm³ cm⁻³) versus SIFSIX-2-Cu-i (42 cm³ cm⁻³). In comparison to other top-performing materials, UTSA-200a exhibits a new benchmark for C_2H_2 uptake at 0.01 bar (Figure 2d), even higher than Mg- and Fe-MOF-74, indicating its ultrastrong C₂H₂ capture capacity at low pressure. Conversely, as revealed by Figure 2b, the smaller static pore size of UTSA-200a can completely prevent the entrance of C₂H₄ molecule below 0.2 bar and has very little uptake ($\approx 0.25 \text{ mmol g}^{-1}$) up to 0.7 bar at 298 K, which is dramatically lower than that of SIFSIX-2-Cu-i (2.28 mmol g^{-1}). When the pressure was further increased to 1 bar, C₂H₄ adsorption isotherm slopes up. This is because the N=N bond and the pyridine rings in the MOF linker have certain rotational flexibility, so the pore sizes were slightly enlarged under higher pressure (larger than 0.7 bar) to take up small amount of C₂H₄ molecules (Figure S8, Supporting Information). Nevertheless, the C_2H_4 uptake amounts of UTSA-200a in the entire range of 1 bar are still the lowest among the indicated materials (Figure S9, Supporting Information). Therefore, our adsorption findings demonstrated that the contracted pore size of UTSA-200a supports to efficiently block C₂H₄ molecules without sacrificing its high C₂H₂ adsorption capacity, rendering UTSA-200a an ideal candidate for C2H2/C2H4 separation at ambient conditions.

To gain further insight into the ultrastrong C_2H_2 adsorption and confirm the calculated C_2H_2 binding sites, high-resolution neutron powder diffraction data were collected on C_2D_2 -loaded samples of UTSA-200a and Rietveld structural refinements were conducted (Figure S11, Supporting Information). After the samples loaded with various amount of C_2D_2 molecules, the MOF lattice can be slightly distorted from the tetragonal symmetry to a monoclinic lattice. As shown in Figure 2e,f, each adsorbed C_2D_2 molecule interacts with two SiF_6^{2-} anions from different nets through cooperative $C-D\cdots F$ H-bonding, which is consistent well with the previous calculated C_2H_2 binding configuration. Because of the smaller pore size, the

experimentally determined H-bonding length in UTSA-200a (1.921 Å) is notably shorter than that observed in SIFSIX-2-Cu-i (2.015 Å), further indicating that there are stronger interactions with C₂H₂ molecules. Consistent with this, the calculated static binding energy (ΔE) of C₂H₂ for UTSA-200a (56.0 kJ mol⁻¹) is larger than that of SIFSIX-2-Cu-i (52.9 kJ mol⁻¹), making it the strongest C₂H₂ adsorption observed in SIFSIX and related materials. This is the primary factor for the ultrahigh C₂H₂ adsorption capacity of UTSA-200a at very low pressures. Further diffraction measurement shows that the MOF structure can be completely restored after removing C₂D₂ from the sample, suggesting that the adsorption-induced lattice distortion is a temporary effect, and thus the sample does not lose crystallinity.

Given the observations of molecular exclusion of C_2H_4 and ultrastrong C_2H_2 capture capacity, UTSA-200a was found to exhibit an extraordinary ideal adsorbed solution theory (IAST) selectivity of over 6000 at 1 bar and 298 K for binary C_2H_2/C_2H_4 (1/99, v/v) mixtures, significantly higher than the previous topperforming materials (**Figure 3**a). It should be pointed out that this value is only for the qualitative comparison purpose. We also calculated the uptake ratios of C_2H_2/C_2H_4 (at 0.01/0.01 or 0.01/0.99 bar) determined from single-component isotherms^[40] and compared with other reported MOFs (Figure S12, Supporting Information). These data also clearly demonstrate the superior selectivity of UTSA-200a for the separation of C_2H_2/C_2H_4 mixtures. In addition, UTSA-200a also exhibits the highest C_2H_2 uptake (1.74 mol kg⁻¹) for adsorption from this gas mixture, which is much higher than the benchmark MOFs evaluated in Figure 3b. UTSA-200a is to our knowledge the first example of a porous material that fully overcomes the trade-off between selectivity and uptake capacity in which it exhibits not only the unprecedented high selectivity but also record-high uptake capacity in the context of C_2H_2/C_2H_4 separation.

Next, transient breakthrough simulations were performed to validate the feasibility of using UTSA-200a in a fixed bed for the separation of $1/99 C_2H_2/C_2H_4$ mixture that mimics the industrial process. Figure 3c reveals the molar concentrations of C₂H₂/C₂H₄ exiting the adsorber packed with UTSA-200a as a function of the dimensionless time, τ , at 1 bar and 298 K. Complete separation was accomplished by UTSA-200a, whereby C₂H₄ breakthrough occurred first within seconds to yield the polymer-grade gas, and then C2H2 passed through the fixed bed after a certain time (τ_{break}). Attributed to the recordhigh selectivity and C_2H_2 uptake capacity, the au_{break} value for UTSA-200a is more than twice as long as that observed in the previous benchmark, SIFSIX-2-Cu-i. Further, during the time $0-\tau_{\text{break}}$, the C₂H₂ amount captured by UTSA-200a reaches up to 2133.3 mmol L⁻¹, which is 3-30 times higher than SIFSIX-2-Cu-i (780.0 mmol L⁻¹) and other benchmark materials (Figure 3d). Overall, the separation performance of UTSA-200a far surpasses other SIFSIX materials and MOFs reported to date.

Comparison of the a) IAST selectivity and b) C_2H_2 uptake capacity of UTSA-200a versus the other best-performing materials. c) Simulated column breakthrough curves for C_2H_2/C_2H_4 separation with respect to various MOF materials as indicated. d) Plots of the amount of C_2H_2 captured as a function of τ_{break} in the simulated column breakthrough for UTSA-200a and the other indicated materials. e) Experimental column breakthrough curves for C_2H_2/C_2H_4 separations with UTSA-200a and the other indicated materials. e) Experimental column breakthrough curves for C_2H_2/C_2H_4 separations with UTSA-200a, SIFSIX-2-Cu-i, SIFSIX-1-Cu, and SIFSIX-3-Zn at 298 K and 1.01 bar. f) The recyclability of UTSA-200a under multiple mixed-gas column breakthrough tests.

These simulated results prompted us to further evaluate the separation performance of UTSA-200a in the actual separation. Experimental breakthrough studies were conducted for a C₂H₂/ C_2H_4 (1:99, v/v) mixture at room temperature. As illustrated in Figure 3e, highly efficient separation for C₂H₂/C₂H₄ mixture was achieved by UTSA-200a: the C₂H₄ gas eluted through the adsorption bed immediately in a high-purity grade (Figure S14, Supporting Information), whereas C2H2 was retained in the packed column over 1500 min (the concentration in the outlet below 40 ppm). This C_2H_2 breakthrough time is 2 times longer than SIFSIX-2-Cu-i (~800 min), in good agreement with the simulated breakthrough results. Detailed gas chromatography data revealed that the purity of C₂H₂ in the outlet effluent was below 1 ppm up to 1300 min, affording high C₂H₄ purity of >99.9999% (Figure S15, Supporting Information). The C₂H₂ concentration is notably less than the acceptable level of <40 ppm for polymer-grade C₂H₄ gas. During the breakthrough process, the C2H4 production from the outlet effluent and the C2H2-captured amount for a given cycle were analyzed to be record high of 85.7 and 1.18 mmol g⁻¹, respectively, which is much higher than the 47.4 and 0.73 mmol g^{-1} observed in SIFSIX-2-Cu-i. The adsorbed C₂H₂ can be further recovered in a two-step process via adsorption followed by desorption at 338 K, offering a 93.6% recovery of a C_2H_2 capacity of 1.105 mmol g⁻¹ per cycle, with a 97% purity (Figures S16 and S17, Supporting Information). This recovered C₂H₂ purity is notably higher than the 89% obtained in SIFSIX-2-Cu-i. These results indicate that UTSA-200a offers the potential to effectively separate C_2H_2 from C_2H_4 and simultaneously produce both gases in high purity.

www.advmat.de

The feed gases in the practical C₂H₂ removal unit are often contaminated by trace levels of CO₂ (<50 ppm), H₂O (<5 ppm), and O₂ (<5 ppm),^[43] so the amenability to recycling and efficacy in the presence of these gases must be also addressed. To investigate the influence of these other gases, we conducted a series of breakthrough experiments on UTSA-200a for the 1/99 mixtures containing trace amounts of CO2, H2O, and O_2 , respectively. The presence of CO_2 (100 ppm) and O_2 (up to 2200 ppm) has a negligible effect on the separation capacity of UTSA-200a (Figures S18 and S19, Supporting Information). Similarly, the moisture (from 6 to 1340 ppm) also did not affect the separation of C₂H₂ from C₂H₄ (Figure S20, Supporting Information). Subsequently, we performed multiple mixed-gas $(C_2H_2/C_2H_4$ at 1/99) column breakthrough tests to examine the preservation of separation performance of UTSA-200a at ambient conditions. The recycling measurements revealed that UTSA-200a retains the C2H2 capture capacity and its molecular sieving over 12 cycles (Figures S21 and S23, Supporting Information). The breakthrough time remains almost unchanged during 12 breakthrough experiments, confirming the recyclability of this material for C_2H_2/C_2H_4 separation (Figure 3f). As inferred from the PXRD performed on associated samples, the framework of UTSA-200a remains stable after multiple adsorption and breakthrough experiments (Figure S27, Supporting Information).

Removal of acetylene from ethylene/acetylene mixture (1/99) is one of the most important but challenging industrial-scale gas separations and is currently affected by energy- and costintensive processes.^[44-46] Although adsorption-based porous materials offer promise to create cost-effective and energy-efficient separation technologies, porous materials reported so far suffer from a trade-off between adsorption capacity and selectivity.^[47-50] We have demonstrated the first example of nearly ideal molecular sieve, UTSA-200a, with the required characteristics (molecular-sieving size of \approx 3.4 Å and strong binding sites toward C₂H₂), that afford the selective molecular exclusion of C_2H_4 and record-high amount of C_2H_2 adsorption, thus overcoming the trade-off effect for achieving highly efficient separation of C₂H₂/C₂H₄ mixtures. The molecular sieving of C₂H₂ from C₂H₄ is supported by detailed structural analysis, gas adsorption isotherms, simulated and experimental breakthrough studies. The resulting separation performance includes record-high C_2H_4 productivity of 87.5 mmol g⁻¹ per cycle with purity higher than 99.9999% and simultaneous production of the high purity C_2H_2 (97%) via a simple recovery operation.

Ideal molecular sieves, while very difficult to achieve, indeed can provide a promising energy-efficient route to address the industrially important gas separations. Through fine tuning of pore size in molecular sieves to selectively exclude the C₂H₄ but to retain the strong binding sites for the record-high C₂H₂ adsorption capacity, our findings demonstrated, for the first time, that it is possible and feasible to target microporous MOFs with ideal molecular sieve performance through the elaborated fine tuning of the pore sizes and the introduction of specific binding sites for the preferred gas molecules. SIFSIX-14-Cu-i/ UTSA-200 can readily remove trace amount of C₂H₂ from 1/99 C₂H₂/C₂H₄ mixture, affording benchmark high selectivity as well as benchmark C₂H₂ capture capacity and thus record-high C₂H₄ production scale as demonstrated in the breakthrough experiments. Combined with the excellent recyclability and resistance to other gases, SIFSIX-14-Cu-i/UTSA-200 represents an ideal microporous solid material that has the potential to be applied in the industry as an adsorbent for removing trace acetylene from ethylene using a relatively simple and energyefficient process. The principle revealed in this work is general, which will provide some guidance to facilitate the design and implementation of ideal molecular sieves for other important gas separations and purification as well.
