Keywords: 2-dimensional material, monolayer molybdenum disulfide (MoS$_2$), operando oxidation, thermochemistry, X-ray absorption spectroscopy (XAS)

Abstract

Monolayer MoS$_2$ is a promising semiconductor to overcome the physical dimension limits of the microelectronic devices. Understanding the thermochemical stability of MoS$_2$ is essential since these devices generate heat and are susceptible to oxidative environments. Herein, we show the promoting effect of molybdenum oxides (MoO$_x$) particles on the thermal oxidation of MoS$_2$ monolayers employing operando XAS, ex-situ SEM, and XPS. We demonstrate that CVD-grown MoS$_2$ monolayers contain intrinsic MoO$_x$ and are quickly oxidized at 100 °C (3 vol % O$_2$/He), in contrast to previously reported oxidation thresholds (e.g., 250 °C, t ≤ 1 h in the air). Otherwise, removing MoO$_x$ increases the thermal oxidation onset temperature of monolayer MoS$_2$ to 300 °C. These results indicate that MoO$_x$ promote oxidation. An oxide-free lattice is critical to the long-term stability of monolayer MoS$_2$ in state-of-the-art two-dimensional electronic, optical, and catalytic applications.
Monolayer molybdenum disulfide (MoS$_2$) is an atomically-thin semiconductor with a sub-nanometer thickness (6.5 Å to 8 Å),$^{[1, 2]}$ high electron mobility ($\approx 200$ cm$^2$ V$^{-1}$ s$^{-1}$),$^{[1]}$ a direct band gap (1.8 eV to 2.2 eV),$^{[1, 3]}$ and high current on/off ratio ($> 10^8$).$^{[1]}$ MoS$_2$ monolayers$^{[4]}$ can potentially be used for flexible electronics and push the physical dimension limits of microelectronics.$^{[4-6]}$ Towards these visions, great progress has been made on the synthesis of wafer-scale polycrystalline MoS$_2$ monolayers,$^{[7]}$ and large-domain ($\approx 500$ µm) single crystalline MoS$_2$ monolayers by chemical vapor deposition (CVD),$^{[2]}$ and the wafer-scale transfer and stacking of monolayer MoS$_2$ for heterogeneous integrations.$^{[8, 9]}$ In practice, microelectronics dissipate energy through Joule heating,$^{[10]}$ and MoS$_2$ monolayer transistors reach average operating temperatures of $> 150$ °C with local hot spots of $> 250$ °C.$^{[10, 11]}$ Therefore, investigating the thermochemical stability of MoS$_2$ above room temperature and under the device working temperature range is important.

Past studies on the thermal oxidation of MoS$_2$ reported that the oxidation process is fast when the temperature is above $\sim 250$ °C (e.g., 250 °C in the air for 1 h,$^{[12]}$ 360 °C in the air for 5 min,$^{[13]}$ and 380 °C in the air for 10 min; Table S1, Supporting Information).$^{[10]}$ These findings were supported by ex-situ observations of pits and crack formation, and identification of molybdenum oxides via atomic force microscopy (AFM),$^{[12-16]}$ scanning electron microscopy (SEM),$^{[13, 15, 17]}$ transmission electron microscopy (TEM),$^{[17]}$ X-ray photoelectron spectroscopy (XPS),$^{[12, 16, 17]}$ nanomechanical means,$^{[16]}$ and Raman spectroscopy.$^{[14]}$ Such ex-situ characterization methods, although very informative, may not detect subtle morphological and chemical compositional changes brought on by MoS$_2$ oxidation. Importantly, the previous thermal oxidation studies assumed chemically pure MoS$_2$ monolayers. However, many reported as-grown monolayers frequently showed an XPS peak indicative of Mo$^{6+}$ 3d$_{3/2}$ from MoO$_3$ at $\sim 236.5$ eV.$^{[14]}$
Even though molybdenum oxides (MoO$_x$) are known to activate and transfer oxygen\cite{20,21} are defective,\cite{22,23} and oxophilic,\cite{24} their effect on the oxidation of MoS$_2$ has not been systematically investigated.

Herein, we characterize the thermal oxidation of MoS$_2$ monolayers with and without MoO$_x$ at atmospheric pressure in the temperature range of 25 °C to 400 °C using a novel ultra-sensitive operando X-ray absorption spectroscopy (XAS). We report the first XAS measurement of an atomically-thin monolayer MoS$_2$ under dynamic environments (i.e., temperature ramping up to 400 °C, 3 vol % O$_2$/He, 101.3 kPa, with X-rays in the energy range of 2 to 3 keV) and it is complemented by ex-situ XAS, SEM, and XPS. Such unique measurements of monolayer species were performed using our newly designed operando XAS reactor that enables an ultra-sensitive electron yield (EY) detection mode under actual reactive environments;\cite{25-29} different to conventional fluorescence and transmission modes (See Table S2 for details, Supporting Information). Our study shows that as-grown MoS$_2$ monolayers via CVD contain trace amounts of oxygenated Mo$^{4+}$ and Mo$^{6+}$. Without removing the MoO$_x$, the oxidation of MoS$_2$ monolayer was activated starting as low as 100 °C even in a diluted oxidative atmosphere at ambient pressure (3 vol % O$_2$ in inert gas). After removing MoO$_x$, the oxidation onset temperature of MoS$_2$ monolayers is increased to 300 °C. Our work shows that an oxide-free and high-purity monolayer MoS$_2$ is critical to the enhanced thermochemical stability of MoS$_2$.

To understand the effect of MoO$_x$ on the MoS$_2$ oxidation, we prepared both as-grown (oxide-containing) and etched (oxide-free) MoS$_2$ monolayers with high quality supported on SiO$_2$/Si wafers (See Experimental Section, Supporting Text and Figures S1-S4 for details, Supporting Information). The etched monolayer MoS$_2$ was prepared by removing MoO$_x$ via an alkaline-bath transfer treatment. We conducted electron microscopy, Raman, and XAS
measurements to confirm that the etching step does not cause a structural and chemical change to the 2H-MoS\textsubscript{2} phase (Figure 1, Figure 2, Figures S1, S2, and S4, see also Supporting Text in the Supporting Information). Ex-situ SEM images in Figure 1 show the morphological evolution of the as-grown and etched MoS\textsubscript{2} monolayers. For all SEM images, the light background indicates the SiO\textsubscript{2}/Si support wafer (blue arrow), and the dark-colored triangular shapes are monolayer MoS\textsubscript{2} (red arrow) with tens of micrometers in size. Both the as-grown and etched MoS\textsubscript{2} samples appear to have unchanged global morphology even after oxidation at 350 °C, and both break up to small pieces at 400 °C (green arrow and dotted circles). The as-grown and some oxidized MoS\textsubscript{2} monolayers have lighter-color nanoparticles arranged in lines (Figure S5, Supporting Information) as marked by orange arrows and guided lines in Figure 1. The nanoparticles are ascribed to molybdenum oxides (MoO\textsubscript{x}, vide infra). In comparison, those MoO\textsubscript{x} nanoparticles are not seen on the etched MoS\textsubscript{2} (Figure 1k and Figure S6, Supporting Information), confirming the successful removal of oxide species by the alkaline treatment, consistent with the Mo Pourbaix diagram.\textsuperscript{[30]}

Finally, for the etched monolayer MoS\textsubscript{2}, cracks and pits start to appear at 300 °C and 350 °C, which are indications of MoS\textsubscript{2} oxidation (Figure 1n,o; and high magnification images in Figure 1r,s), and are also observed in the as-grown MoS\textsubscript{2} at the same annealing temperatures (Figure 1d,e; and high magnification images in Figure 1h, i). Overall, the SEM results suggest that the oxidation onset temperature of MoS\textsubscript{2} monolayer is around 300 °C, regardless of the presence of MoO\textsubscript{x} nanoparticles, which is consistent with previous oxidation studies.\textsuperscript{[12-14]}

The operando XAS characterization reveals the details of the oxidation behavior differences for MoS\textsubscript{2} monolayers with and without MoO\textsubscript{x}, which are not captured by SEM images. Our new operando XAS reactor equipped with EY detection mode enables, for the first-time, XAS measurement of atomically thin MoS\textsubscript{2} monolayers under reactive conditions, see the experimental
scheme of the reactor in Figure S7 and Table S2, Supporting Information). The X-ray beam spot size of 1 mm (vertical) x 3 mm (horizontal) is much larger than the single crystalline domain size of the monolayers (tens to around 100 µm). First, X-ray absorption near edge structure (XANES) spectra of reference standards were obtained in the EY mode under He atmosphere under ambient pressure at room temperature using commercial bulk MoS₂, MoO₂, and MoO₃ materials. The obtained spectra are consistent with the literature and our theoretical calculations (Figures S8 and S9, Supporting Information). Then, the S K-edge and Mo L₃,₂-edge XANES spectra of the as-grown and etched MoS₂ monolayers were measured under He atmosphere at room temperature. Though their spectra are similar to the bulk MoS₂ material as shown in Figure 2, the as-grown MoS₂ monolayer shows additional shoulder peaks (black arrows) at 2528.6 eV in the Mo L₃-edge (Figure 2b) and 2633.5 eV in the Mo L₂-edge (Figure 2c), which indicates the presence of MoOₓ.

After confirmation of the existence of MoOₓ in the as-grown MoS₂ monolayers, operando XAS under the oxidative atmosphere was performed to follow the differences between the as-grown and etched MoS₂ monolayers with increasing temperature. The oxygen partial pressure used in the operando XAS electron yield reactor (3 vol % O₂/He, 101.3 kPa) was identical to that used for the ex-situ XAS, SEM, and XPS studies. The MoS₂ monolayers were ramped to the desired temperature and held there for 30 minutes. Then, three consecutive overlapping XAS scans were recorded that show spectra reproducibility (Figure S10, Supporting Information), and the averaged spectra are used here. Figure 3 shows the operando XANES spectra of as-grown (Figure 3a,c) and etched (Figure 3b,d) MoS₂ monolayers under increasing temperatures (100 °C to 400 °C). The chemical evolutions of the as-grown and etched MoS₂ samples were monitored by following the S K-edge (Figure 3a,b) and Mo L₃-edge (Figure 3c,d) XANES spectra.
The evolution of the S K-edge spectra is similar for the MoS\(_2\) monolayers with and without oxides. Both S K-edge spectra features of the as-grown and etched MoS\(_2\) monolayers match with the bulk MoS\(_2\) references for temperatures up to 350 °C, indicating that S atoms remain in the MoS\(_2\) chemical composition (Figure 3a,b). At 400 °C, both S K-edge spectra show a new peak at 2482.6 eV, which is ascribed to S\(^{6+}\), likely in the form of sulfates.\(^{[31]}\) The difference in the intensity of the new S\(^{6+}\) peaks at 400 °C indicates that the as-grown sample oxidizes more than the etched monolayer MoS\(_2\) (Figure 3a,b). The formation of sulfates at 400 °C coincides with the severe morphological changes observed via SEM images (Figure 1f,p).

On the other hand, the operando Mo L\(_3\)-edge XANES spectra show different evolution features between the as-grown and etched MoS\(_2\) monolayers (Figure 3c,d). Those spectra were further subtracted by the spectra of the etched monolayer at 25 °C (i.e., pristine MoS\(_2\) without oxides) to obtain the difference spectra (Figures 3e,f), which highlight the changes of spectra feature. For the as-grown MoS\(_2\) monolayer, the first negative broad feature at 2524.5 eV ascribed to a combination of Mo\(^{4+}\) and Mo\(^{6+}\) grows with increasing temperature up to 300 °C. Then, the negative feature shifts 0.3 eV to lower energy, resembling Mo\(^{6+}\) as in the MoO\(_3\) reference (Figure 3e). Likewise, the Mo L\(_3\)-edge spectra show a gradually increased Mo\(^{6+}\) peak at 2528.6 eV with increasing temperature (Figure 3c,e). Finally, the Mo L\(_3\)-edge white line is shifted from resembling MoS\(_2\) to MoO\(_3\) at 400 °C (Figure 3c,e). In comparison, for the etched sample, the Mo\(^{4+}\) and Mo\(^{6+}\) peaks ascribed to MoO\(_2\) and MoO\(_3\) become slightly apparent only at 300 °C, and the Mo L\(_3\)-edge white line is shifted from resembling MoS\(_2\) to MoO\(_3\) at 400 °C (Figure 3d,f). The Mo L\(_2\)-edge spectra show the same trends (Figure S11, Supporting Information). We cross-checked the operando XAS results by conducting ex-situ XAS of those MoS\(_2\) monolayers shown in Figure 1, and the results are consistent (Figure S12, Supporting Information). First-principles simulations of
XAS spectra with the OCEAN code\textsuperscript{[32, 33]} show that O-substitution on S-vacancies in MoS\textsubscript{2} monolayers produces a sequential shift of the absorption edge with increasing oxygenation as observed in our experimental spectra (Figure 3c,e, and Figure S13, Supporting Information). To summarize the Mo L\textsubscript{3}-edge operando XANES results, oxygenated Mo\textsuperscript{4+} and Mo\textsuperscript{6+} species are formed starting at 100 °C in the as-grown MoS\textsubscript{2} monolayer sample, and those species increase with increasing temperature (likely in the form of MoO\textsubscript{2} and MoO\textsubscript{3}). In contrast, features ascribed to oxides start to appear at 300 °C for the etched MoS\textsubscript{2} monolayer sample. Furthermore, the as-grown MoS\textsubscript{2} monolayers are nearly completely oxidized at 400 °C, at which point, Mo\textsuperscript{6+} species (as in MoO\textsubscript{3}) dominate the spectra; however, the etched MoS\textsubscript{2} monolayers still show a transition towards MoO\textsubscript{3} formation at 400 °C likely resulting in the spectral combination of MoO\textsubscript{2} and MoO\textsubscript{3} signals.

To quantitively investigate the trend of chemical composition changes of the as-grown and etched MoS\textsubscript{2} monolayers at different temperatures, the linear combination fitting analysis (LCFA) of the operando Mo L\textsubscript{3}-edge XANES from Figure 3c,d was performed,\textsuperscript{[34]} and the results are presented in Figure 3g,h (see Table S3 and S4 for details, Supporting Information). First, the chemical analysis supports the existence of MoO\textsubscript{x} in the as-grown MoS\textsubscript{2} monolayer, and on the contrary, the etched sample is composed of pure MoS\textsubscript{2}. Second, the amount of MoO\textsubscript{x} in the as-grown sample is found to gradually increase with increasing temperature even at the low temperature of 100 °C, indicating the oxidation onset temperature (1±1 % MoO\textsubscript{2} and 3±1 % MoO\textsubscript{3} increase, and 5±1 % MoS\textsubscript{2} decrease). Third, the oxidation of the etched MoS\textsubscript{2} monolayer starts at 300 °C. Complementarily, the normalized sulfur concentration acquired from the S K-edge step as a function of temperature is shown in Figure S14, Supporting Information. The analysis of the edge step in the S K-edge XANES spectra shows that both the as-grown and etched MoS\textsubscript{2}
monolayers start losing significant amounts of S at around 350 °C, indicating that rapid oxidation happens. Both as-grown and etched MoS$_2$ monolayers undergo severe chemical transformations at 400 °C. The as-grown monolayer MoS$_2$ loses on average ≈ 23 % more sulfur than the etched MoS$_2$ monolayer under the same high temperatures and oxidation conditions at 350 °C and 400 °C. Overall, the differences between the samples in XANES and the chemical analysis suggest that the presence of MoO$_x$ lowers the onset temperature for fast thermal oxidation, promotes the oxidation reaction under the same temperature, and facilitates the sulfur loss in monolayer MoS$_2$. Building upon published literature on the catalytic properties of oxides of molybdenum,\textsuperscript{[20, 21]} we propose that MoO$_x$ facilitates O$_2$ dissociation ultimately lowering the onset oxidation temperature of as-grown MoS$_2$ monolayers down to 100 °C.

We further conducted complementary ex-situ XPS at the O 1s, Mo 3d, and S 2p regions to confirm the impact of MoO$_x$ on the oxidation process of MoS$_2$ monolayers. Figure 4a,d show the O 1s spectra of the as-grown and etched MoS$_2$ monolayers which are fitted with two singlets, respectively. The main peak at 533.4 eV for both samples is assigned to Si-O from the SiO$_2$/Si substrate.\textsuperscript{[35]} The small peak at 531.4 eV corresponds to lattice Mo-O in oxide structures.\textsuperscript{[12, 36, 37]} For the as-grown MoS$_2$ monolayer, the O 1s peak intensity of Mo-O gradually increases from room temperature to 400 °C, so does the Mo$^{6+}$ peaks at 236.5 eV (3d$_{3/2}$) and 233.5 eV (3d$_{5/2}$) in the Mo 3d region (Figure 4b).\textsuperscript{[12, 38, 39]} For the etched-MoS$_2$ layers, both the O 1s peak for Mo-O and the Mo$^{6+}$ peaks are negligible below 300 °C (Figure 4d,e). The S 2p spectra show no significant differences throughout the oxidation process until 400 °C for both as-grown and etched samples (Figure 4c,f). For both as-grown and etched samples, the MoS$_2$ monolayers seem to be nearly fully oxidized at 400 °C (Mo$^{6+}$ > 90 % approximately, Figure S15, Supporting Information), as evidenced by the weak intensity of S 2p (Figure S16, Supporting Information; 10 times magnified
counts than in Figure 4f) and 2s peaks, and Mo$^{4+}$ peaks at 233.3 eV (3d$^{3/2}$) and 230.2 eV (3d$^{5/2}$) in
the Mo 3d region.$^{[12, 38, 39]}$ The XPS results support the observations from the operando XANES
spectra (Figure 3) in that MoO$_x$ activates the oxidation of MoS$_2$ monolayer from the low
temperature at 100 °C. Nevertheless, operando XANES shows advantages by providing
quantitative and qualitative information of chemical changes with better sensitivity, such as the
sulfur loss and chemical specificity with increasing temperature under reactive and dynamic
environmental conditions. Ultimately, operando XAS provides the accurate chemical composition
evolution of the reaction products under the actual working conditions of two-dimensional devices.

In summary, we reveal for the first time the low-temperature thermal oxidation of
monolayer MoS$_2$ promoted by MoO$_x$. Our pioneering ultra-sensitive operando XAS study shows
that the as-grown MoS$_2$ monolayers (via CVD) contain MoO$_2$ and MoO$_3$ impurities (i.e., MoO$_x$)
and that the amount of the oxides increase with increasing MoS$_2$ oxidation even with exposures to
diluted O$_2$ at the low-temperature of 100 °C (3 vol % O$_2$/He, 101.3 kPa). In comparison, the etched
MoS$_2$ monolayers remain pristine until heating to 300 °C. The difference indicates that MoO$_x$
promotes the oxidation of MoS$_2$ monolayers under the operation conditions of two-dimensional
devices. The available S atoms remain in a similar chemical and structural environment up to
350 °C, at which point MoS$_2$ oxidizes to MoO$_3$ and other volatile species. These results are
supported by systematic ex-situ XAS, XPS, and SEM characterizations. The results demonstrate
that the oxide-free condition is critical to the long-term thermochemical stability of monolayer
MoS$_2$; which is expected to hold for other transition metal dichalcogenides monolayers with
crucial implications for emerging scalable two-dimensional electronic, optical, and catalytic
applications.
